

Association Rule Mining

1. Get online Retail dataset from <http://archive.ics.uci.edu/ml/datasets/Online+Retail>
It consists of 541909 instances with 8 attributes.
 - a. Write a function to choose unique 'k' items from the dataset.
 - b. Write a function to find the customers who bought items from a given list of 'k' items and output in the form of a transaction matrix.
2. Frequent k-itemset.- $L(k)$
 - a. Given a support threshold 's', write a function to find the k-itemset having support greater than 's'.
3. Candidate itemset
 - a. Given two frequent k-itemset, $L(k)$, generate $L(k+1)$
4. Given an itemset with cardinality 'T', and confidence threshold 'c', write a function to output the possible association rules with confidence greater than 'c'.
5. Repeat 2,3,4 for the dataset 'store_data.csv'
6. Follow <https://www.geeksforgeeks.org/implementing-apriori-algorithm-in-python/> to use in-built apriori algorithm.
